RED CRACKING CLAY

General Description: Red crumbly clay with a lichen crust, becoming finer textured, harder, and more calcareous and coarsely structured with depth

Landform: Gilgai plain (patterned plain)

with shelf and hollow microrelief and variable

scalding

Substrate: Heavy clay with well

developed slickensides

Vegetation: Grassland with some

perennial shrubs. Dominant

species:

Eragrostis setifolia Sclerolaena diacantha Panicum decompositum

Type Site: Site No.: CU034

Location: Bindarrah Station Sampling date: 08/02/1994

1:50,000 mapsheet: 7033-4

Easting: 472800 Northing: 6446950

Annual rainfall: 195 mm average

Site in a gilgai depression with a cracking, lichen encrusted surface and minor quartz gravel.

Soil Description:

Depth (cm)

Description

0-10 Red light clay with strong granular structure and

minor quartz gravel. Abrupt to:

Dark red moderately calcareous heavy clay with

moderate very coarse polyhedral structure and

minor quartz gravel. Gradual to:

30-60 Dark reddish brown highly calcareous heavy clay

with strong very coarse polyhedral structure and

minor quartz gravel. Diffuse to:

Dark red highly calcareous heavy clay with strong

very coarse polyhedral structure and minor quartz

Classification: Epicalcareous-Epihypersodic, Epipedal, Red Vertosol; non-gravelly, fine / very fine, deep

gravel. Gradual to:

100-130 Red highly calcareous heavy clay with strong very

coarse lenticular structure and 2-10% soft

carbonate segregations.

Summary of Properties

Drainage: This soil becomes temporarily waterlogged (a few days) after heavy rain due to its

high clay content.

Fertility: The exchangeable cation data indicate that the soil has a very high capacity to store

plant nutrients, right to the surface. This condition is helped by the relatively high

organic carbon content at the surface.

pH: Alkaline to strongly alkaline throughout.

Rooting depth: 100 cm in pit. There are very few roots below this depth.

Barriers to root growth:

Physical: The high strength of the clay may impede the development of the roots of some

species.

Chemical: The sodium content (ESP) is high, but unlikely to be a problem because the calcium

levels are very high. The boron concentration is very high (by agricultural standards) from 60 cm and this may affect root growth. Very high pH from 30 cm and high salt content from 100 cm, affect some species. The soil has a low carbonate (lime content)

and high clay content, which affect species suitability.

Waterholding capacity: Approximately 120 mm. The high clay content gives this soil a high wilting point - a

high percentage of rainfall is bound on to the clay and is not available for plant

uptake.

Seedling emergence: Good.

Erosion Potential: This soil has a low potential for erosion, and will absorb substantial amounts of water

except in heavy rain storms.

100-130	8.1	8.0	3.7	5.57	13.8	0.1	14	243	-	57.3	1.3	5	1.4	0.3	34.4	18.1	6.79	9.04	1.02	25.9

Note: Paddock sample bulked from cores (0-10 cm) taken around the pit.

CEC (cation exchange capacity) is a measure of the soil's capacity to store and release major nutrient elements.

ESP (exchangeable sodium percentage) is derived by dividing the exchangeable sodium value by the CEC.
